Executive Summary

A systemically important institution can tolerate many things. An intelligence layer that can be switched off, priced up, or retired by someone else is not one of them.

As institutions move core operations onto AI, that intelligence becomes infrastructure, as load-bearing as power, networks, and payments. Infrastructure has one non-negotiable property: continuity. Yet the dominant way of consuming AI, renting it from a small number of external providers, makes continuity contingent on a party the institution does not control. Outages, export controls, model deprecations, and price shocks are each a switch held by someone else, and any one of them can interrupt a capability the institution can no longer operate without. This paper argues that for consequential institutions, intelligence continuity is not a service level to negotiate but a property to own, and that owned, sovereign intelligence is the only form that delivers it: no external party can withdraw it, throttle it, or force it to change.

In Brief

- As AI becomes core to operations, it becomes infrastructure, and infrastructure must be continuous; interruption is not an acceptable state.
- Rented intelligence makes continuity contingent on an external party through four kill-switches: outages, export controls, deprecations, and price shocks.
- Owned intelligence is continuity by design; no outside party can withdraw, throttle, or force-upgrade it.
- Version continuity matters as much as uptime: you hold your vintage, and capability change is your decision, not a vendor push.
- Treat intelligence as critical infrastructure, with the continuity guarantees a regulated institution already demands of power and networks.

The test of an infrastructure is not how well it runs on a good day. It is whether anyone outside the institution can stop it running at all.

1. Intelligence Becomes Infrastructure

The moment an institution cannot perform its core function without AI, that AI has become infrastructure, whether or not anyone decided to treat it as such.

Institutions are moving decisions, operations, and increasingly actions onto AI, and as they do, the intelligence layer crosses a threshold: it stops being a tool that improves the work and becomes a dependency the work cannot proceed without. That is the definition of infrastructure. And infrastructure carries an obligation that ordinary software does not, because when it fails the institution does not merely slow down, it stops. A stock exchange, a bank, a hospital, a utility, a government service: none can accept an intelligence layer that is available most of the time, any more than it would accept power or networks on those terms.

The day an institution cannot function without its AI is the day that AI became infrastructure, and infrastructure that can be switched off from outside is a liability, not an asset.

2. The Four Kill-Switches

Renting intelligence does not remove the risk of interruption. It relocates the switch to a party the institution does not control.

A rented intelligence layer can be interrupted in four distinct ways, and each is held by someone other than the institution that depends on it. Outages: the provider's system fails, and the institution's operations fail with it. Export controls: a government restricts access across a border, and a capability the institution built its operations around becomes unavailable overnight. Deprecations: the provider retires or changes the model, and the behaviour the institution validated and depends on is gone. And price shocks: the provider re-prices consumption, and a cost the institution treated as fixed becomes a lever pulled against it. None of these is a remote contingency; each has already happened in the short history of the technology.

> **"Dependence on a small number of external providers for a critical capability is itself a systemic risk, regardless of how reliable any single provider may be."**
> International Monetary Fund, on concentration and operational resilience · 2026. [3]

3. Continuity Is More Than Uptime

Even a provider that never has an outage can break continuity, because continuity includes the right to keep the intelligence you have.

There is a form of interruption that has nothing to do with availability: the forced change. A rented model is retired, deprecated, or altered on the provider's schedule, and the institution that validated its behaviour, built processes around it, and satisfied a regulator with it is compelled to move to something new that must be validated all over again. For a casual user an upgrade is a gift; for an institution running a governed process, a forced change is a discontinuity, because the thing it certified no longer exists. Version continuity, the right to hold your vintage and change only when you choose, is as much a part of continuity as uptime, and rented intelligence does not provide it.

An upgrade you did not ask for is an interruption you did not plan. Continuity means the capability changes when you decide, and not before.

4. If This Goes Unattended

Build critical operations on an interruptible foundation and the institution is not running a risk it can price. It is running one it cannot see the timing of.

Left unattended, the exposure is not a probability to manage but a dependency to dread, because the institution controls neither whether an interruption comes nor when. A provider outage during a market open, an export control during a geopolitical rupture, a deprecation the week before an audit, a price change that turns a budgeted cost into a crisis: each is outside the institution's control and inside its critical path. And as more of the institution's operations move onto the intelligence layer, the blast radius of any one of these grows, until an external party's routine decision, to retire a model, to change a price, to comply with its own government, becomes an operational emergency for an institution on another continent.

The institution that rents its critical intelligence has not bought a capability. It has bought a dependency whose interruption is scheduled by someone else, on terms it will learn about after the fact.

5. Continuity by Design

Continuity cannot be negotiated into a rental. It is a property of owning the intelligence and running it where no one else can reach the switch.

Owned, sovereign intelligence is continuous by construction, because the conditions that interrupt a rented layer do not apply to it. It cannot be subject to a provider outage, because there is no external provider in the critical path. It cannot be cut off by an export control, because it already runs inside the institution's own boundary. It cannot be deprecated against the institution's will, because the institution holds its own vintage and decides when capability changes. And it cannot be re-priced as a lever, because its cost is a fixed, owned investment rather than a meter someone else controls. Continuity stops being a service level the institution hopes the provider honours and becomes a property of the architecture the institution owns.

You cannot contract your way to continuity from a party who holds the switch. You can only own the switch yourself.

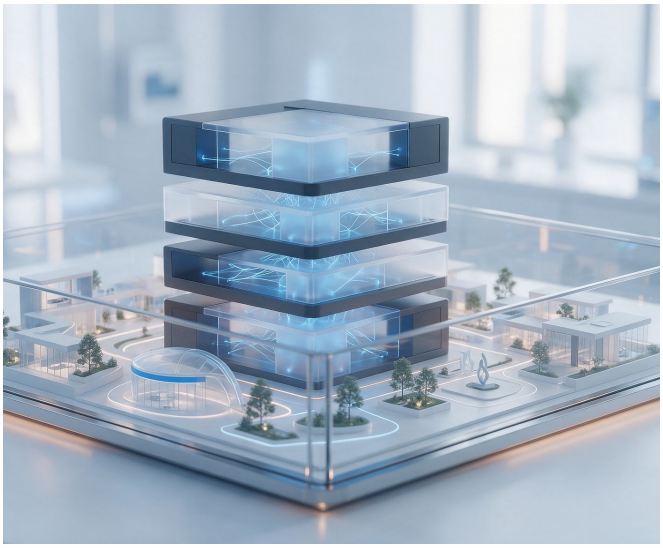
6. What Leaders Must Do



The move is to treat intelligence with the seriousness already applied to every other critical infrastructure the institution runs on.

Make continuity a procurement gate, not a feature request: an intelligence layer that can be interrupted by an outside party should not carry a critical operation, just as a single-sourced, remotely-controlled power supply would not. Require ownership and sovereign deployment for anything on the critical path, hold your own model vintage so capability change is your decision, and treat the intelligence layer to the same continuity standards, redundancy expectations, and independence requirements the institution already applies to power, networks, and payments.

An institution already refuses to run on power it cannot count on. Intelligence has become the same kind of thing, and deserves the same refusal.

Action	What it guarantees
Classify critical AI as infrastructure	It is held to continuity standards, not treated as ordinary software
Own and deploy within the boundary	No external outage or control sits in the critical path
Hold your own model vintage	Capability changes on the institution's schedule, not the vendor's
Fix the cost as an owned investment	Price cannot be used as a lever against the institution
Make continuity a procurement gate	Interruptible intelligence is disqualified from critical operations

7. The Choice

Every institution putting core operations on AI is deciding, whether it means to or not, who holds the switch.

The choice is between an intelligence layer that runs at the pleasure of an external provider and one the institution owns and cannot be cut off from. For a casual application, the first is fine. For a systemically important operation, only the second is defensible, because continuity is not a feature of critical infrastructure, it is the definition of it. The institution that treats intelligence continuity as it treats the continuity of power and networks will still be operating

Foresight here is simple. The institutions that own their intelligence will run without interruption. The ones that rent it will run until someone else decides otherwise.

About This Series

Sovereign Perspectives is a research program on the ownership and governance of intelligence, published by Concierto. Its papers examine the strategic, economic, and institutional questions that artificial intelligence raises for governments and other accountable institutions, and they are written for the leaders making those decisions. The program's aim is to advance the public argument, not to promote a product.
