7. The Reframe

About This Series · Sources

## At a Glance

**142x** fewer parameters now match a 2022 flagship

**1.7%** gap between open and closed models, down from 8%

**11.9→5.4%** the gap between the best model and the tenth, in a year

## In Brief

- The assumption that more scale means more capability is breaking down: smaller and specialized models now match far larger general ones on the tasks that matter.
- The top models are converging, so paying for the very largest buys a shrinking advantage over the rest.
- On any specific domain, a model built for that domain beats a general giant, because scale buys breadth an enterprise does not need.
- Chasing the largest model locks a buyer into the largest suppliers and spends capital on generality it will never use.
- The path to usable, affordable intelligence is a purpose-built model an enterprise or nation can own, not the biggest one it can rent.

# Executive Summary

The industry has spent five years equating intelligence with size, and the assumption is now failing on its own numbers. A model 142 times smaller than a 2022 flagship matches its performance today, the gap between the best model and the tenth has collapsed from 11.9 percent to 5.4 percent in a single year, and open models have closed to within 1.7 percent of the best closed ones. The frontier is converging, the returns to scale are shrinking, and a model built for a purpose now beats a giant built for everything. This paper argues that specialization, not scale, is the path to intelligence an enterprise or a nation can actually use and afford.

**The most capable intelligence for a purpose is rarely the largest. It is the one built for that purpose.**

# 1. The Cult of Scale

For most of the modern AI era, one idea has organized the field: bigger is better. More parameters, more data, more compute, and the leaderboard would follow. The idea was right for a time, and it produced the leap that put AI on every agenda. It has also become a habit of thought that outlived the evidence, because it flatters the few who can afford the largest models and frames every other choice as a compromise. The result is a market that measures intelligence by size and treats the biggest model as the safe default, even for tasks that never needed it.

**Scale was the story of the last five years. It is not the same as the story of the next five.**

# 2. The Evidence Says Otherwise

The numbers have turned against the assumption. A 2024 model of under four billion parameters matches the performance of a 2022 flagship more than a hundred times its size, a 142-fold reduction in two years. Meanwhile the field is converging: the gap between the best model and the tenth best fell from 11.9 percent to 5.4 percent in a single year, and the gap between open and closed models narrowed from 8 percent to 1.7 percent. The advantage of being the very largest is shrinking toward the margin of measurement error.

**5.4%**

**The distance between the best model and the tenth is now smaller than the gap most enterprises could ever exploit.**

## 3. Why Specialization Wins

Convergence at the top only sharpens the real point, which is what a model is for. A general model is trained to be adequate at everything, which means it carries enormous capability that any given user never touches, and pays for it in cost, latency, and unpredictability.

A model built for a domain, grounded in that domain's data and shaped to its tasks, spends its capacity where the work is. On the task that matters, the specialized model is not a smaller compromise; it is the more accurate instrument, because accuracy on a domain comes from fit, not from raw size.

This inverts the default. The question a buyer should ask is not how large a model can afford, but how well a model fits the work. Scale answers a question few enterprises are actually asking, which is how to be mediocre at everything at once. Specialization answers the one they are: how to be excellent at the thing they do.

**Scale buys breadth an enterprise will never use. Specialization buys depth in the one thing it does.**

## 4.The Cost of Chasing Scale

There is a deeper reason scale disappoints, and it is a curve, not a wall. Capability from raw scale follows an S-curve, steep at first and then flattening as each added order of magnitude of parameters and compute buys less than the last. The frontier is now on the flattening part of that curve, which is why models a fraction of the size match giants on real tasks. Once scale saturates, the advantage stops going to whoever deploys the most intelligence and starts going to whoever deploys the best-fitted intelligence, which is the whole case for specialization. Diminishing returns on brute force is not a caveat to the thesis; it is the proof of it.

Defaulting to the largest model is not a neutral choice; it compounds against the buyer. It ties the enterprise to the handful of suppliers that can field frontier-scale models, on their pricing and their terms. It spends capital on generality that never touches the work. And it accepts the cost and latency of a model doing far more than the task requires, on every call, forever. As the returns to scale shrink, the premium paid for the largest model buys less and less, while the dependency it creates only deepens.

**Shrinking The advantage bought by the largest model is shrinking every year, even as the lock-in it creates grows.**

# 5. The Ways Out

There is more than one response, and they are not equal.

| RENT THE LARGEST GENERAL MODEL | OWN A PURPOSE-BUILT MODEL |
|---|---|
| Adequate at everything, excellent at nothing in particular | Excellent at the domain it is built for |
| Pays for breadth the enterprise never uses | Spends its capacity where the work is |
| Locks the buyer to the few frontier suppliers | Owned, grounded in the buyer's own data |
| A shrinking advantage at a fixed premium | A widening fit as the model learns the domain |

Renting the largest general model is the path of least resistance, and for open-ended exploration it has its place. But for the work an enterprise or a nation actually depends on, the specialized, owned model is both more accurate and more affordable, and it improves as it is used because the owner keeps the record of that use.

**The right model for the work is not the largest one available. It is the one built for the work and owned by the one who does it.**

## 6. What Leaders Must Do

The reframe is a procurement and strategy decision before it is a technical one.

- Measure fit, not size. Evaluate models by accuracy on the actual task, not by parameter count or leaderboard rank.
- Default to purpose-built. Reserve the largest general models for open exploration, and build or own specialized models for the work that matters.
- Ground it in your own data. A specialized model grows more accurate the more of the domain's data it is grounded in, which is a reason to own it.
- Refuse the scale premium. Stop paying for generality the enterprise will never use, and redirect the capital toward capability it will.

> **142x If a model that small can match a giant, the case for defaulting to the giant has already collapsed.**

## 7. The Reframe

The age of scale delivered the breakthrough, and it deserves the credit. But it also trained a reflex, to reach for the biggest model for every job, that now costs more than it returns. The evidence points the other way: capability is converging, size is a shrinking advantage, and the intelligence an enterprise or a nation can actually use and afford is the one built for its purpose and held as its own. The frontier of usefulness is no longer the largest model. It is the best-fitted one.

> **The next advantage in AI belongs not to whoever rents the largest model, but to whoever builds the best-fitted one and owns it.**

## About This Series

Sovereign Perspectives is a research program on the ownership and governance of intelligence, published by Concierto. Its papers examine the strategic, economic, and institutional questions that artificial intelligence raises for governments and other accountable institutions, and they are written for the leaders making those decisions. The program's aim is to advance the public argument, not to promote a product.
